1.1 *Conceptual Exercises*

1.1.1 (5) It is well-known that ridge regression tends to give similar coefficient values to correlated variables, whereas the lasso may give quite different coefficient values to correlated variables. We will now explore this property in a very simple setting.

1.1.2 Suppose that $n = 2$, $p = 2$, $x_{11} = x_{12}$, $x_{21} = x_{22}$. Furthermore, suppose that $y1 + y2 = 0$ and $x_{11} + x_{21} = 0$ and $x_{12} + x_{22} = 0$, so that the estimate for the intercept in a least squares, ridge regression, or lasso model is zero: $\hat{\beta}_0 = 0$.

1.1.3 (a) Write out the ridge regression optimization problem in this setting.

Solution: The regular *ridge regression* fitting procedure minimizes $L(\beta)$ such that:

$$L(\beta) = \underbrace{\sum_{i=1}^{n} \left(y_i - \beta_0 - \sum_{j=1}^{p} \beta_j x_{ij}\right)^2}_{RSS} + \lambda \sum_{j=1}^{p} \beta_j^2$$

Supposing that $n = 2$, $p = 2$, and

$$x_{11} = x_{12}, \qquad x_{21} = x_{22}.$$

... and that:

$$y_1 + y_2 = 0, \qquad x_{11} + x_{21} = 0, \qquad x_{12} + x_{22} = 0,$$

... with the intercept in least squares, ridge, or lasso is zero: $\hat{\beta}_0 = 0$.

We have *ridge regression* problem by solving the minimization problem considering the equation, as seen in this chapter:

$$L(\hat{\beta}) = \min_{\hat{\beta}_1, \hat{\beta}_2} \sum_{i=1}^{2} \left(y_i - x_{i1}\hat{\beta}_1 - x_{i2}\hat{\beta}_2\right)^2 + \lambda \left(\hat{\beta}_1^2 + \hat{\beta}_2^2\right).$$

with λ being the regularization parameter.

Using the facts $x_{11} = x_{12}$ and $x_{21} = x_{22}$, this can rewrite the optimization problem as follows:

$$\boxed{L(\hat{\beta}) = \min_{\hat{\beta}_1, \hat{\beta}_2} \left(y_1 - x_{11}(\hat{\beta}_1 + \hat{\beta}_2)\right)^2 + \left(y_2 - x_{21}(\hat{\beta}_1 + \hat{\beta}_2)\right)^2 + \lambda \left(\hat{\beta}_1^2 + \hat{\beta}_2^2\right).}$$

1.1.4 (b) Argue that in this setting, the ridge coefficient estimates satisfy $\hat{\beta}_1 = \hat{\beta}_2$.

Solution: From part (a), with $x_{11} = x_{12}$ and $x_{21} = x_{22}$, the ridge objective is

$$L(\hat{\beta}_1, \hat{\beta}_2) = (y_1 - x_{11}(\hat{\beta}_1 + \hat{\beta}_2))^2 + (y_2 - x_{21}(\hat{\beta}_1 + \hat{\beta}_2))^2 + \lambda(\hat{\beta}_1^2 + \hat{\beta}_2^2).$$

The data-fit term depends only on the sum $s = \hat{\beta}_1 + \hat{\beta}_2$.

For any $(\hat{\beta}_1, \hat{\beta}_2)$, let $m = (\hat{\beta}_1 + \hat{\beta}_2)/2$ and $d = (\hat{\beta}_1 - \hat{\beta}_2)/2$.

Replacing $(\hat{\beta}_1, \hat{\beta}_2)$ by (m, m) keeps s and the fit unchanged, but changes the penalty to

$$\hat{\beta}_1^2 + \hat{\beta}_2^2 = (m+d)^2 + (m-d)^2.$$

Expanding,

$$= 2m^2 + 2d^2 = 2m^2 + \frac{(\hat{\beta}_1 - \hat{\beta}_2)^2}{2}.$$

Since $\frac{(\hat{\beta}_1 - \hat{\beta}_2)^2}{2} \geq 0$, we have

$$\hat{\beta}_1^2 + \hat{\beta}_2^2 \;\geq\; 2m^2,$$

and, when equality holds $\implies \hat{\beta}_1 = \hat{\beta}_2$.

Thus, the ridge penalty is minimized when $\hat{\beta}_1 = \hat{\beta}_2$.

Since the loss part depends only on s, the overall minimizer must satisfy

$$\boxed{\hat{\beta}_1 = \hat{\beta}_2}.$$

1.1.5 (c) Write out the lasso optimization problem in this setting.

Solution: The regular *lasso* fitting procedure minimizes $L(\beta)$ such that:

$$L(\beta) = \underbrace{\sum_{i=1}^{n} \Big(y_i - \beta_0 - \sum_{j=1}^{p} \beta_j x_{ij} \Big)^2}_{RSS} + \lambda \sum_{j=1}^{p} |\beta_j|$$

With $\hat{\beta}_0 = 0$, $x_{11} = x_{12}$, and $x_{21} = x_{22}$, the *lasso objective* is

$$L(\beta) = \min_{\beta_1, \beta_2} \sum_{i=1}^{2} \Big(y_i - x_{i1}\beta_1 - x_{i2}\beta_2 \Big)^2 \;+\; \lambda(|\beta_1| + |\beta_2|).$$

Using $x_{11} = x_{12}$ and $x_{21} = x_{22}$, this can be written equivalently as

$$\boxed{L(\beta) = \min_{\beta_1, \beta_2} \Big(y_1 - x_{11}(\beta_1 + \beta_2) \Big)^2 + \Big(y_2 - x_{21}(\beta_1 + \beta_2) \Big)^2 \;+\; \lambda(|\beta_1| + |\beta_2|).}$$

1.1.6 (d) Argue that in this setting, the lasso coefficients $\hat{\beta}_1$ and $\hat{\beta}_2$ are not unique—in other words, there are many possible solutions to the optimization problem in (c). Describe these solutions.

Solution: Since $x_{11} = x_{12}$ and $x_{21} = x_{22}$, the data-fit depends only on the sum $s = \beta_1 + \beta_2$.

For fixed s, we must minimize $|\beta_1| + |\beta_2|$ subject to $\beta_1 + \beta_2 = s$.

By the triangle inequality (see reference below),

$$|\beta_1| + |\beta_2| \;\geq\; |\beta_1 + \beta_2| \;=\; |s|,$$

with equality **iff** β_1 and β_2 have the **same sign** (zeros allowed).

Therefore the lasso reduces to the **univariate** problem

$$s^\star = \min_s \ \mathrm{RSS}(s) + \lambda|s|,$$

which has a unique minimizer $s^\star$.

Every pair $(\hat{\beta}_1, \hat{\beta}_2)$ with

$$\hat{\beta}_1 + \hat{\beta}_2 = s^\star \quad \text{and} \quad \mathrm{sign}(\hat{\beta}_1) = \mathrm{sign}(\hat{\beta}_2) = \mathrm{sign}(s^\star)$$

achieves the same objective value.

When

$$\hat{\beta}_1 = t \implies \hat{\beta}_2 = s^\star - t$$

Hence, if $s^\star \neq 0$, there is a **set of solutions**:

$$\mathbb{S} = \{s^\star \text{ such that } (\hat{\beta}_1, \hat{\beta}_2) = (t,\, s^\star - t) : \begin{cases} t \in [0, s^\star]\} & \text{if } s^\star \geq 0\} \\ t \in [s^\star, 0]\} & \text{if } s^\star \leq 0\}. \end{cases}$$

(If $s^\star = 0$, the unique solution is $(0, 0)$.) □

test_mae  = mean_absolute_error(y_test, y_pred)

print("PLS Model:")
print("---------")
print(f"Total encoded predictors (p): {p_total}")
print(f"Selected number of components (M): {best_M}")
print(f"Test MSE : {test_mse:,.2f}")
print(f"Test RMSE: {test_rmse:,.2f}")
print(f"Test MAE : {test_mae:,.2f}")
print(f"Test R^2 : {test_r2:,.3f}")
```

```
PLS Model:
---------
Total encoded predictors (p): 17
Selected number of components (M): 17
Test MSE : 1,085,881.76
Test RMSE: 1,042.06
Test MAE : 646.07
Test R^2 : 0.912
```

1.2.8 (g) Comment on the results obtained. How accurately can we predict the number of college applications received? Is there much difference among the test errors resulting from these five approaches?

Accuracy of predictions
- All methods achieve **high accuracy**: $R^2 \approx 0.91$, meaning ~91% of the variance in `Apps` is explained by the predictors.

Differences among methods
- **OLS, Ridge, PCR, and PLS** all yield **essentially the same** test error (MSE 1,085,882; RMSE 1,042; $R^2 \approx 0.912$).
- Ridge chose a **tiny** λ (1e-4) $\rightarrow$ effectively **OLS**.
- **PCR/PLS** selected $M = p = 17 \rightarrow$ they replicate the **OLS** fit. - **Lasso** is slightly better: **MSE 1,058,263; RMSE 1,028.7; MAE 630.9;** $R^2 = 0.915$ with **14/17** non-zero coefficients.

- Gains vs OLS: **MSE ↓ ~2.54%**, **RMSE ↓ ~1.28%**, **MAE ↓ ~2.35%**, $R^2 = +0.003$.

Comments
- You can predict `Apps` (the number of applications received) **quite well** with these features.
- **No large differences** among methods for this split; **Lasso** offers a **small** improvement and a **simpler** model (14/17 coefficients).
